

HW#2 problem 5

- You are to compute the averages of the following, averaged over the three classes:
 - true positive rate
 - false positive rate
 - error rate
 - the accuracy
 - the precision
- That is, compute each one for class A, each for class B, and each one for class C, then average all three
 - E.g., $\text{TPR} = (\text{TPR}_A + \text{TPR}_B + \text{TPR}_C)/3$
 - $\text{FPR} = (\text{FPR}_A + \text{FPR}_B + \text{FPR}_C)/3$
 - ...
- But how to compute these for a three-class problem?

Two-class:

		Actual class \mathcal{C}		
		1	0	
Predicted class $\hat{\mathcal{C}}$	1	TP	FP	<i>Estimated positive \hat{P}</i>
	0	FN	TN	<i>Estimated negative \hat{N}</i>
		<i>Positives P</i>	<i>Negatives N</i>	TOTAL

Three-class, for class A:

		Actual class \mathcal{C}			
		A	B	C	
Predicted class $\hat{\mathcal{C}}$	A	TP	FP		
	B	FN	TN		
	C				

True positives in white entry

False negatives – sum the orange entries

False positives – sum the blue entries

True negatives – sum the pink entries

Three-class, for class B:

		Actual class \mathcal{C}		
		A	B	C
Predicted class $\hat{\mathcal{C}}$	A	TN	FN	TN
	B	FP	TP	FP
	C	TN	FN	TN

Three-class, for class C:

		Actual class \mathcal{C}		
		A	B	C
Predicted class $\hat{\mathcal{C}}$	A			FN
	B			FN
	C	FP		TP

True positives in white entry

False negatives – sum the orange entries

False positives – sum the blue entries

True negatives – sum the pink entries
